1. Introduction

Aging is a significant risk factor for many neurological and psychiatric disorders. While the effects of healthy aging have been consistently reported in resting-state EEG and MEG data, a formal comparison of these modalities in capturing such effects remains lacking.

Objectives

Here we contrast the ability of two modalities to detect the effects of healthy aging by investigating:

(1) how static and dynamic resting-state network (RSN) features represent healthy aging in each modality (2) whether EEG or MEG show higher sensitivity to such effects in source space

2. Data & Methods: Dynamic Brain Network Modeling Transition HMM State Time Course **Probability Matrix** Resting-state States Eyes-closed EEG LEMON [1] MEG CamCAN [2] Time $\boldsymbol{\gamma} \in \mathbb{R}^{K \times K}$ **Observational Model for Each RSN State Dynamic Network Features** 98 subjects Young (20-35 years) Mean Covariance PSD Old (55-80 years) Power 60 young, 36 old HMM Parameters Variational $\theta = \{\gamma, \mu, D\}$ subjects **Bayesian Inference Dynamic Modeling** Q^{-} Objective Function: **Time-Delay Embedded Minimize variational free energy** $\mathbf{D} \in \mathbb{R}^{K \times M \times M}$ $\mathbf{u} \in \mathbb{R}^{K \times M}$

Hidden Markov Model (TDE-HMM) [3]

Dataset

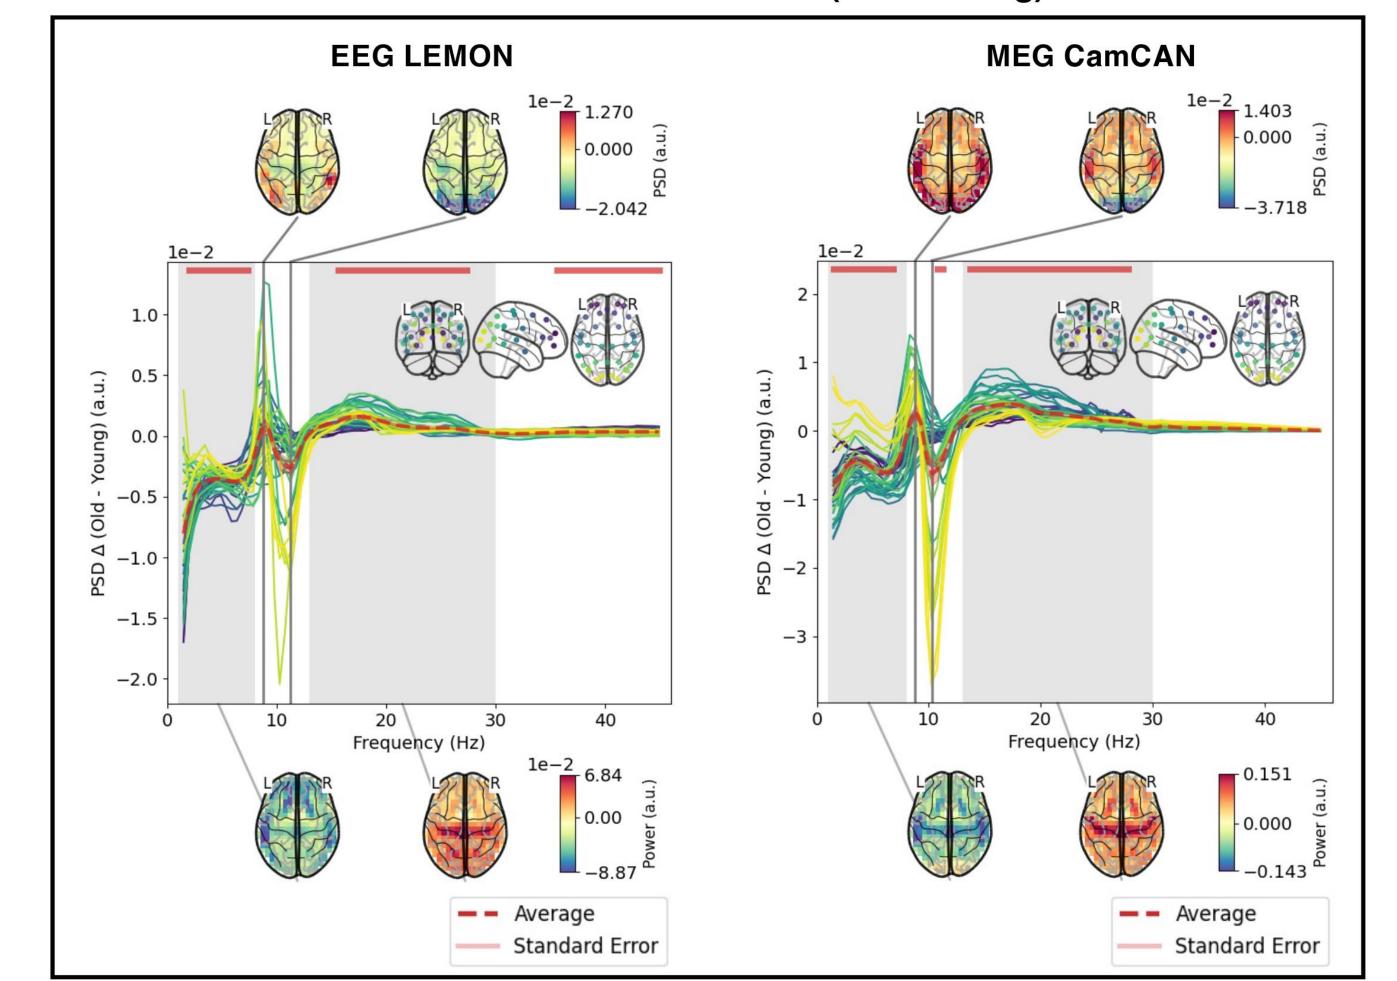

Groups

	-	

K = # states; M = # channels

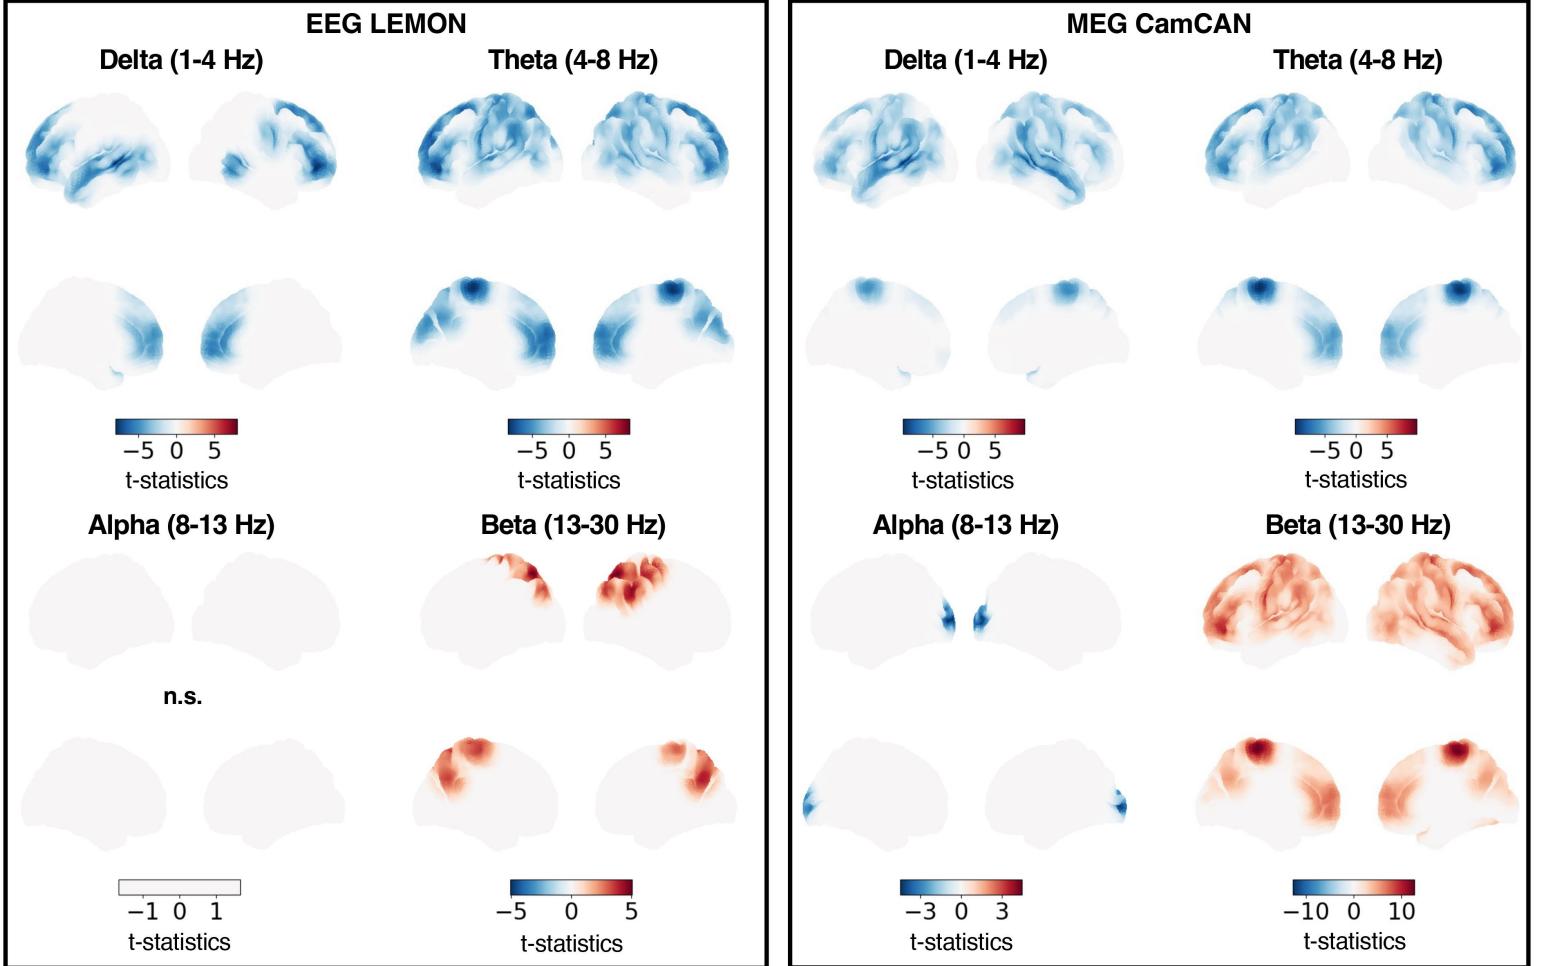

3. Resting-state M/EEG reveal comparable age effects in static PSDs and power maps within source space

Parcel-averaged power spectral densities (PSDs) show **similar** age effects in the delta/theta (1-8 Hz) and beta (8-13 Hz) bands across modalities.

- Static PSD Differences (Old Young)
- Static narrow-band power maps show **comparable** age effects across modalities.
- A few caveats are (1) non-significance in EEG alpha power & (2) enhanced effects in MEG delta and beta powers.

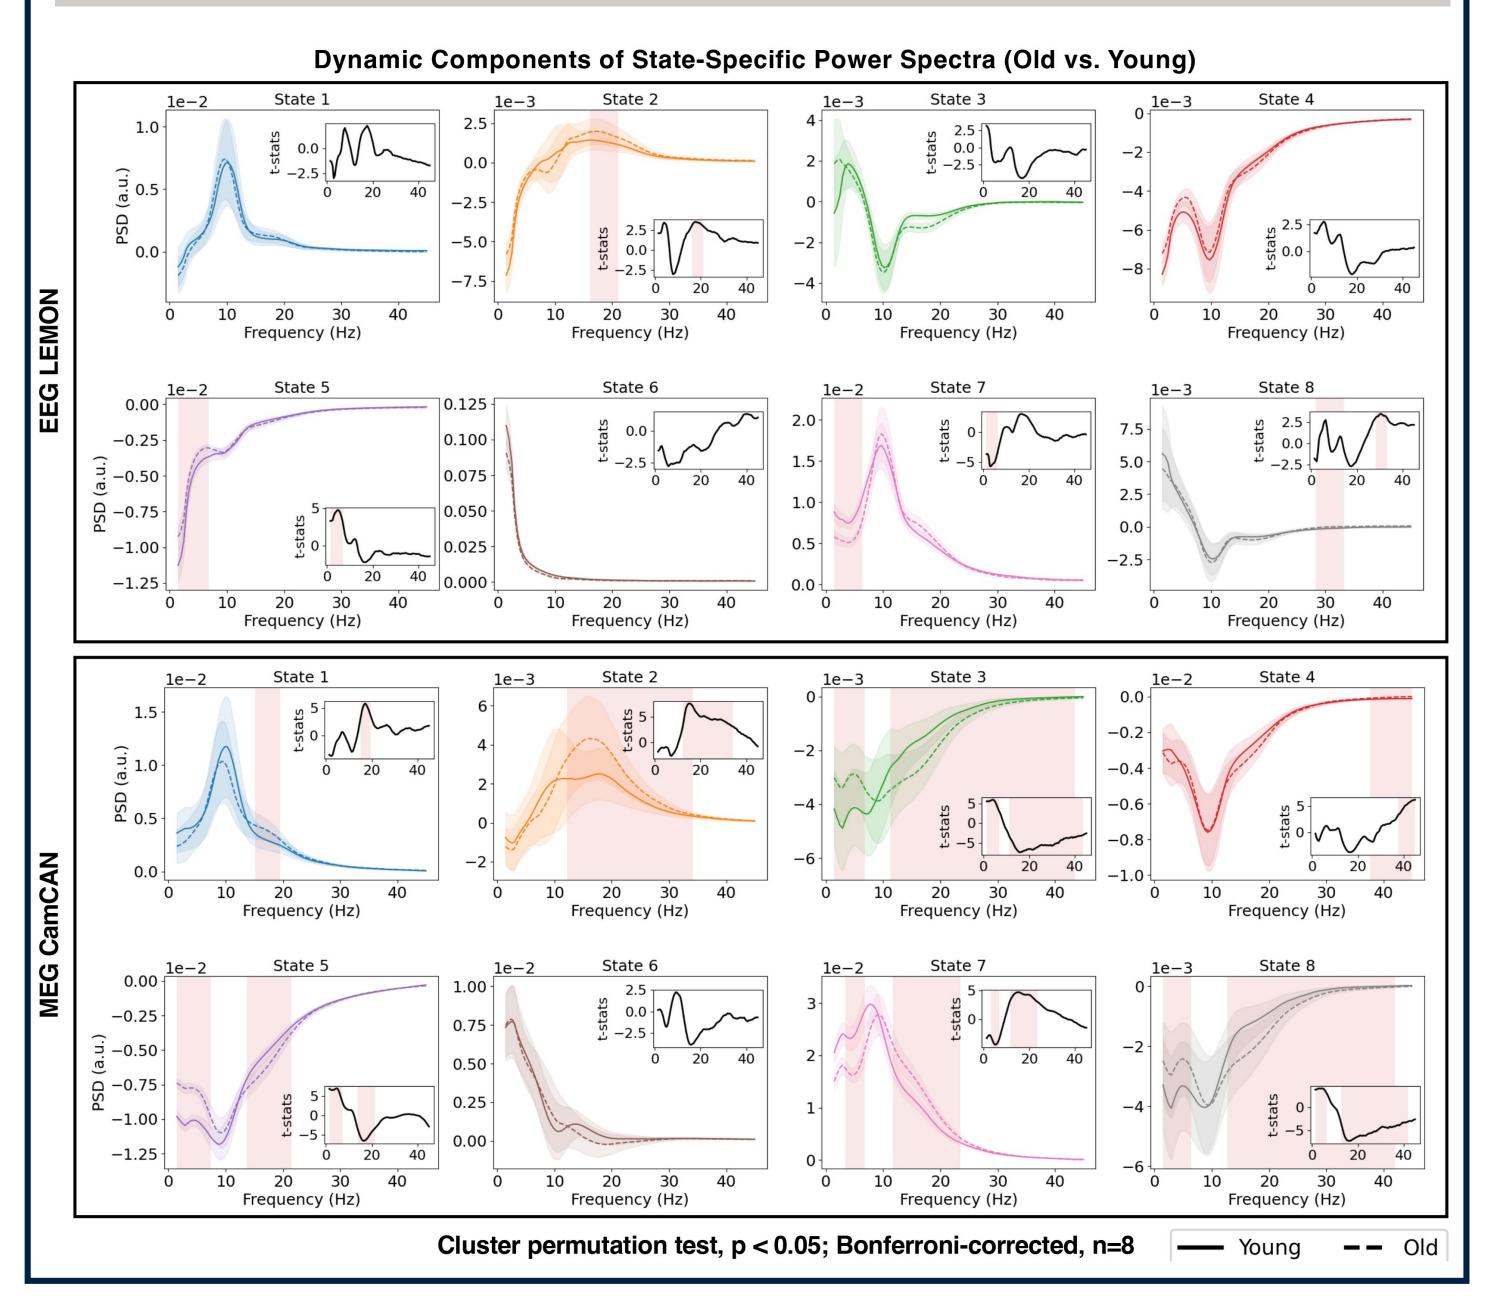

Cluster permutation test; significance as red bar (p < 0.05)

n.s.: non-significant (Max-t permutation test, p < 0.05; Bonferroni-corrected, n=4)

4. M/EEG report distinct sets of dynamic RSNs with agerelated effects in PSDs

Age effects in dynamic state-specific PSDs (averaged over parcels)

- Age effects in static PSDs are **distributed** across states in both M/EEG.
- MEG unveil more states with age effects than EEG.
- Sets of states with age effects are **distinct** between modalities.
- Same state may reveal **different effects** across modalities. For instance:
- \circ EEG State 7 \rightarrow significant group differences in delta frequencies
- \circ MEG State 7 \rightarrow significant group differences in theta and beta frequencies

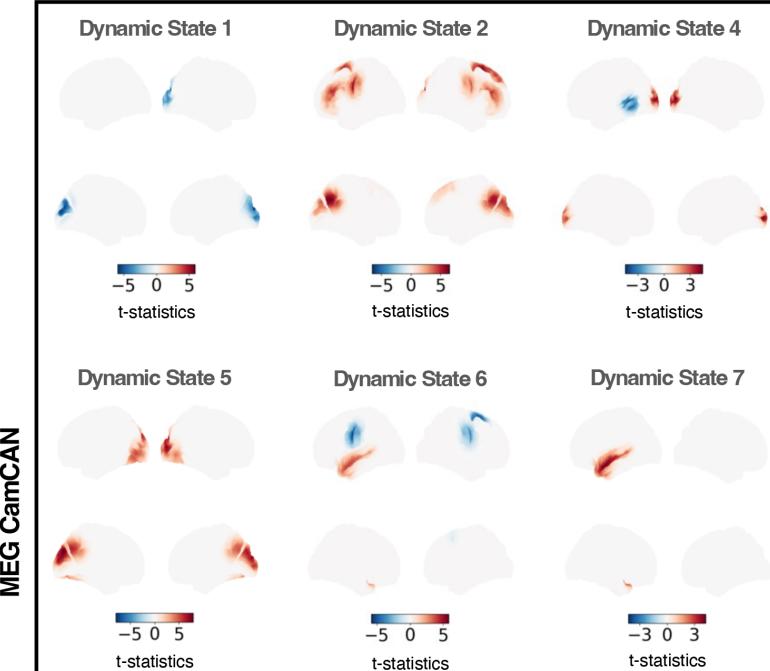

5. Dynamic age effects in state-specific power maps are observed solely in MEG

Age effects in dynamic state-specific power maps (averaged over wide-band, 1-45 Hz)

- Only reported in **MEG** HMM state powers
- States 1, 4, 6, 8
 - Decreased activity in occipital, temporal, and central sulcus regions with age
- States 2, 4, 5, 6, 7
- Increased activity in frontal, occipital, and temporal regions with age
- : While age effects are observed across different HMM states in MEG, they are absent in EEG.
- ∴ This suggests that in the source space, MEG may have **higher sensitivity** to age effects

Dynamic Components of State-Specific Power Maps (Old vs. Young; thresholded)

than EEG, although the use of different datasets and a larger number of sensors in MEG need to be considered.

5. Conclusion

(1) Age effects in the **static** PSDs and power maps are generally analogous across different frequency bands within source space in both MEG and EEG. (2) However, age effects in the **dynamic** RSN features are distinct across modalities, with MEG exhibiting higher sensitivity to such effects than EEG.
